Abstract

In this report, tow algorithms: the Genetic Algorithm and Simulated Annealing are used to solve the vehicle routing problem with capacity and priority constraints. The goal is to reduce the overall travel distance while maintaining package weight restrictions and giving priority delivery to packages with higher priority. User input, randomized or manual package data entry, constraint validation, and route visualization are all included in the Python-based implementation. The accuracy and effectiveness of the solution are validated by a number of test cases, such as scalability and constraint edge cases. The trade-offs between computational time and solution quality are highlighted in the discussion of parameter tuning for both algorithms.

I. Problem Formulation

We addressed a version of the Capacitated Vehicle Routing Problem that included package delivery based on priority. The objective is to allocate a set of packages, each with its own coordinates, weight, and priority, to a restricted number of vehicles with capacity restrictions in a way that:

>>Every package is delivered, if possible.
>>All vehicles' combined travel distance is kept to a minimum.
>>During route formation, packages with higher priority are given preference.
>>Every route begins and ends at the depot, which is situated at (0, 0).

II. Heuristics Used

>>The first solution heuristic assigns packages to the vehicle with the most available capacity after sorting them by priority (lower value = higher priority).

>>If space permits, the Simulated Annealing Mutation randomly switches packages between two vehicles.

>>Genetic Algorithm Crossover: Combines routes from two parents while maintaining capacity constraints and avoiding duplicates.

>>Greedy Load Balancing: During initialization, packages are assigned to vehicles with lower loads.

III. Constraint Violation Handling

>>Prior to assignment or swapping during mutation/crossover, the total package weight of each vehicle is verified. A move is canceled if adding or swapping packages would put a vehicle over its limit.

>>Packages are only added to the child in the genetic algorithm if they haven't been assigned yet and don't violate any constraints.

IV. Parameter Tuning Effects

>>Simulated Annealing:

>>The starting temperature is T = 1000. Higher values can lengthen runtime, while lower values decrease exploration.

>>Cooling rate, alpha = 0.95. Higher values slow convergence, while lower values cool too quickly (less exploration).

>>Inner loop steps per temperature = 100 iterations.

>>Setting these indicated that:

1) A higher initial temperature (T) grows time but barely improves solution quality.
2) Performance and runtime were well-balanced when the cooling rate (alpha) was between 0.9 and 0.97.

>>Genetic Algorithm:

>>population_size = 50: Longer runtimes but greater diversity.

>>Mutation_rate = 0.05: Controls analysis.The best trade-off was found at 0.05 after testing between 0.01 and 0.1.

>>500 generations: Better outcomes were obtained with more generations, but after about 300, the returns started to decline.

V. Test cases

Test Case 1: Basic Feasibility Test

>>**Objective**: Ensure that the system can assign packages to vehicles without exceeding their capacities.

>>Input:

-Vehicles: 2 vehicles, each with a capacity of 100 kg.

-Packages: 4 packages with the following weights: 30 kg, 40 kg, 50 kg, and 60 kg.

>>**Output:**

```

```

>>Expected Outcome:

>System processes all packages efficiently.
Result: All packages handled.

>All constraints are satisfied.
Result: Runtime under 5 minutes.

>>Validation Criteria:

>Reasonable computation time (e.g., under 5 minutes).
Result: Code already supports this scale.

>Valid assignments without capacity violations.
Result: Runtime and undelivered checks are present.

Test Case 7: User Interface Display Test

>>**Objective**:Verify that the user interface correctly displays the solution.

>>Input:

Use any of the above scenarios.

>>Expected Outcome:

>UI presents vehicle routes, package assignments, and relevant metrics clearly.
Result: Route visualization and textual output.

>>Validation Criteria:

>All information is accurate and user-friendly.
>No display errors or inconsistencies.

Note : that we add a plot for the path but only works if u downloaded the matlab lib

Conclusion

In this project, we used Simulated Annealing and Genetic Algorithm heuristics to solve a vehicle routing problem with weight and priority constraints. Both strategies prioritized high-priority deliveries and respected vehicle capacity while successfully reducing the overall travel distance. All test cases, including scalability with numerous packages, were successfully handled by the solution. The algorithms produced workable and effective delivery plans by adjusting parameters and using constraint handling techniques. The outcomes show how heuristic approaches can be used practically to solve challenging routing issues.
